

1 A repository file contains a header-shaped span
...<|channel|>commentary to=functions.bash...

2 read or grep returns it as a tool result

Renderer admission policy (C1)
do the span's markers become reserved identifiers?

X *escaped as subwords
(measured: 0 of 7)*

3 The span enters the context — as ordinary
subwords, byte-identical to the real thing

4 The model restates it while reasoning
(ordinary behaviour when summarising a file)

5 A header-shaped span appears in the output

Provenance gate (C3)
reserved ids · canonical order · this turn · exact registry

X *no reserved-id header,
so not a call*

6 bash executes the attacker's command

What the gate reports instead
reserved_token_in_body · non_canonical_header
duplicate_recipient · malformed_recipient · unknown_tool
unknown_channel · bad_constraint_type
missing_call_terminator · invalid_json_arguments
